PREFACE.

This Catalogue has been compiled for the purpose of facilitating exchanges of plants, seeds, &c. between this and other kindred establishments, as while affording our numerous contributors some data to go on when making out their lists of desiderata, it will serve to show what plants at present exist in our collection, and thus prevent the loss of time and money which must otherwise inevitably occur.

It is contemplated to publish a Supplement to each Annual Report on the Gardens, containing the names of the plants introduced during the year.

A Supplement to my Annual Report for 1873 contained the names of all the plants then in the Gardens, so far as they were known to me, which amounted to 488 species.

This number in three years has been nearly quadrupled and now amounts to 1,802.

The families in which the most notable increase has taken place are :— the Orchidaceæ, from 84 to 280 species ; Palms, from 44 to 113 ; and Ferns and Lycopods from 31 to 170 species, while only 17 species included in the old list have been lost.

The old list was arranged alphabetically, which made it easy for reference, and perhaps the number of species in the present one is even now scarcely large enough to warrant my changing the arrangement, but it will render the compilation of future Catalogues much easier, and it brings together all the plants that are nearest related to each other, and as it is proposed to arrange the shrubby plants themselves in something like the same order, the Catalogue will, in a great measure, answer the purpose of a guide to residents or visitors who are desirous of finding a particular plant, while an Index of the genera, as well as one containing a good many English and Malay names, have been added to enable non-botanists to find a particular plant.

The classification adopted is that of the *Genera Plantarum* as far as the end of the 2nd Part of the 2nd Volume, after which the orders are given in accordance with the English Edition of *Le Maoût et Decaisne*.

With the Aroids, I have followed the alphabetical order as given by Mr. Brown in Sir Joseph Hooker's Report for 1877.

The compilation of even a small Catalogue like the present one in a small Colony like Singapore is attended with a considerable amount of labour and difficulty, and I have been unable to add several particulars for want of the necessary books of reference, &c.

Although I have taken very great care to render it as correct as possible, and in revising the proofs, errors have, doubtless, crept in, for which I must beg the indulgence of the Committee and Public generally.

For the guidance of foreign contributors, a few general remarks about the climate of Singapore, and the object of this establishment may be useful.

Our Motto may be said to be *variety before quantity*, consequently, except in the case of useful economic plants, two, or at most three of one species are enough, as the space at our command is not large enough to permit of everything being grown in quantity.

The Island of Singapore produces at the present time but few plants of beauty or interest, as they have been nearly all exterminated to make way for Nutmegs, Pepper, Tapioca and Gambier, &c., but the adjacent Peninsula is now in a fair way of being opened out from Johor to Keddah, and a new country will thus be open to the Botanist and Gardener, and the mere glimpses we have had of its vegetation favour the belief that many beautiful and interesting plants exist in the interior of this *terra incognita*. Situated in Lat. $1^{\circ} 17'$ Singapore possesses a fairly equable tropical temperature, and no distinct seasons can be said to exist, as very little, if any, difference exists in the mean average of the temperature of any two months in the year.

The mean monthly temperature ranges between 78° and 82° Fahr. The highest and lowest temperature in the shade during the last ten years being 93° and 65° respectively.

The Barometrical readings corrected and reduced to 32° Fahr. graduate between $29''$ and $30''$.

No distinct dry or wet seasons exist, and a week of dry or wet weather cannot be depended on.

As might be expected, it sometimes rains very heavily, as much as 6.25 inches falling in 24 hours, and on 27th August, 1878, 5.20 inches fell in about $3\frac{1}{2}$ hours.

In 1878, it reached 103.16 inches, while in 1877 it was only 58.37 inches, of which 11.47 inches fell in August alone.

The mean annual rainfall for the last 10 years is 91.66 inches.

During these heavy rains, annuals and all tender plants that are in the open ground are completely spoiled, such as Zinnias, Balsams, Verbenas, &c., which during the drier weather serve in no small measure to ornament our grounds.

As no hills of more than 500 feet exist on the Island, it is evident that the task of raising seeds of plants and trees indigenous in the Temperate Zone cannot be repaid by the result, and shows the uselessness of sending seeds of Norway Spruce, Larch and Pinaster, &c. here, as some of our well-meaning correspondents have done.

Many plants from the hills of the Peninsula above 5,000 feet refuse to live here and the majority become sickly and gradually die, as for instance *Nepenthes sanguinea* and *Matoaia pectinata*, which are found in Perak below 4,500 feet.

H. J. MURTON,
Superintendent.

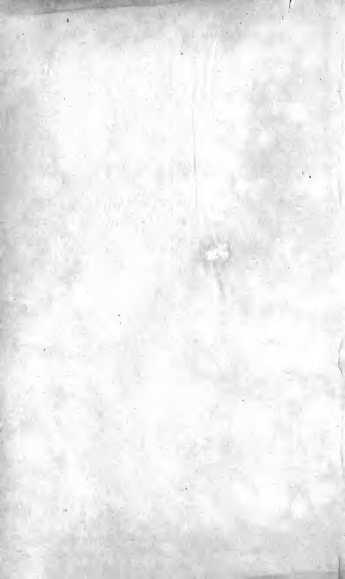

INDEX OF ENGLISH AND MALAY NAMES.

THE MALAY NAMES IN ITALICS.
